The human immunodeficiency virus ("HIV") is the causative agent for acquired immunodeficiency syndrome ("AIDS") -- a disease characterized by the destruction of the immune system, particularly of CD4⁺ T-cells, with

attendant susceptibility to opportunistic infections -- and its precursor AIDS-related complex ("ARC") -- a syndrome characterized by symptoms such as persistent generalized lymphadenopathy, fever and weight loss.

5 As in the case of several other retroviruses, HIV encodes the production of a protease which carries out post-translational cleavage of precursor polypeptides in a process necessary for the formation of infectious virions (S. Crawford et al., "A Deletion Mutation in the
10 5' Part of the pol Gene of Moloney Murine Leukemia Virus Blocks Proteolytic Processing of the gag and pol Polyproteins", J. Virol., 53, p. 899 (1985)). These gene products include pol, which encodes the virion RNA-dependent DNA polymerase (reverse transcriptase), an
15 endonuclease, HIV protease, and gag, which encodes the core-proteins of the virion (H. Toh et al., "Close Structural Resemblance Between Putative Polymerase of a Drosophila Transposable Genetic Element 17.6 and pol gene product of Moloney Murine Leukemia Virus", EMBO J., 4, p. 1267 (1985); L.H. Pearl et al., "A Structural Model
20 for the Retroviral Proteases", Nature, pp. 329-351 (1987); M.D. Power et al., "Nucleotide Sequence of SRV-1, a Type D Simian Acquired Immune Deficiency Syndrome Retrovirus", Science, 231, p. 1567 (1986)).

25 A number of synthetic anti-viral agents have been designed to target various stages in the replication cycle of HIV. These agents include compounds which block viral binding to CD4⁺ T-lymphocytes (for example, soluble CD4), and compounds which interfere with viral
30 replication by inhibiting viral reverse transcriptase (for example, didanosine and zidovudine (AZT)) and inhibit integration of viral DNA into cellular DNA (M.S. Hirsh and R.T. D'Aquila, "Therapy for Human

005030-191650

Immunodeficiency Virus Infection", N.Eng.J.Med., 328, p. 1686 (1993)). However, such agents, which are directed primarily to early stages of viral replication, do not prevent the production of infectious virions in chronically infected cells. Furthermore, administration of some of these agents in effective amounts has led to cell-toxicity and unwanted side effects, such as anemia and bone marrow suppression.

More recently, the focus of anti-viral drug design has been to create compounds which inhibit the formation of infectious virions by interfering with the processing of viral polyprotein precursors. Processing of these precursor proteins requires the action of virus-encoded proteases which are essential for replication (Kohl, N.E. et al. "Active HIV Protease is Required for Viral Infectivity" Proc. Natl. Acad. Sci. USA, 85, p. 4686 (1988)). The anti-viral potential of HIV protease inhibition has been demonstrated using peptidyl inhibitors.

More recently several small molecule protease inhibitors have become available for the treatment of HIV infections. Among these is the sulfonamide-containing molecule, Agenerase® (amprenavir). Agenerase® is described in United States patent 5,585,397. Other sulfonamide inhibitors of aspartyl protease are described in United States patents 5,691,372, 5,510,388, 5,521,219, 5,639,769, 5,714,605, 5,744,481, 5,786,483, 5,830,897 and 5,843,946.

Because HIV-infected patients often develop resistance to particular protease inhibitors, the need still exists for additional compounds that can effectively inhibit the action of aspartyl proteases, particularly HIV protease, for use as agents for

The present invention provides a novel class of compounds, and pharmaceutically acceptable derivatives thereof, that are useful as inhibitors of aspartyl proteases, in particular, HIV aspartyl protease. These compounds can be used alone or in combination with other therapeutic or prophylactic agents, such as anti-virals, antibiotics, immunomodulators or vaccines, for the treatment or prophylaxis of viral infection.

According to a preferred embodiment, the compounds of this invention are capable of inhibiting HIV viral replication in human CD₄⁺ T-cells. These compounds are useful as therapeutic and prophylactic agents to treat or prevent infection by HIV-1 and related viruses which may result in asymptomatic infection, AIDS-related complex ("ARC"), acquired immunodeficiency syndrome ("AIDS"), or similar disease of the immune system.

According to another preferred embodiment, the compounds of this invention are useful as therapeutic and prophylactic agents to treat or prevent infection by HIV mutants.

It is a principal object of this invention to provide a novel class of sulfonamides which are aspartyl protease inhibitors, and particularly, HIV aspartyl protease inhibitors. The novel sulfonamides of this invention are those of formula I:

DETAILED DESCRIPTION OF THE INVENTION

In order that the invention herein described may be
more fully understood, the following detailed description

is set forth. In the description, the following terms are employed herein:

Unless expressly stated to the contrary, the terms "-SO₂-" and "-S(O)₂-" as used herein refer to a sulfone or sulfone derivative (i.e., both appended groups linked to the S), and not a sulfinate ester.

For the compounds of formula I, and intermediates thereof, the stereochemistry of OR⁷ is defined relative to D on the adjacent carbon atom, when the molecule is drawn in an extended zigzag representation (such as that drawn for compound of formula I). If both OR⁷ and D reside on the same side of the plane defined by the extended backbone of the compound, the stereochemistry of OR⁷ will be referred to as "syn". If OR⁷ and D reside on opposite sides of that plane, the stereochemistry of OR⁷ will be referred to as "anti".

The term "alkyl", alone or in combination with any other term, refers to a straight-chain or branch-chain saturated aliphatic hydrocarbon radical containing the specified number of carbon atoms, or where no number is specified, preferably from 1 to about 15 and more preferably from 1 to about 10 carbon atoms. Examples of alkyl radicals include, but are not limited to, methyl, ethyl, n-propyl, isopropyl, n-butyl, isobutyl, sec-butyl, tert-butyl, pentyl, isoamyl, n-hexyl and the like.

The term "alkenyl," alone or in combination with any other term, refers to a straight-chain or branched-chain mono- or poly-unsaturated aliphatic hydrocarbon radical containing the specified number of carbon atoms, or where no number is specified, preferably from 2 to about 18 carbon atoms and more preferably, from 2 to about 8 carbon atoms. Examples of alkenyl radicals include, but

are not limited to, ethenyl, propenyl, isopropenyl, 1,4-butadienyl, pentenyl and the like.

5 The term "alkoxy" refers to an alkyl ether radical, wherein the term "alkyl" is defined above. Examples of suitable alkyl ether radicals include, but are not limited to, methoxy, ethoxy, n-propoxy, isopropoxy, n-butoxy, isobutoxy, sec-butoxy, tert-butoxy and the like.

10 The term "aryl," alone or in combination with any other term, refers to a carbocyclic aromatic radical (such as phenyl or naphthyl) containing the specified number of carbon atoms, preferably from 6-15 carbon atoms, and more preferably from 6-10 carbon atoms, optionally substituted with one or more substituents selected from C1-6 alkoxy, (for example methoxy), nitro, 15 cyano, -SCH₃, halogen, (for example chloro), amino, carboxylate and hydroxy. Examples of aryl radicals include, but are not limited to phenyl, naphthyl, indenyl, indanyl, azulenyl, fluorenyl, anthracenyl and the like.

20 The term "heterocyclyl" or "heterocycle" refers to a stable 3-7 membered monocyclic heterocyclic ring or 8-11 membered bicyclic heterocyclic ring which is either saturated or unsaturated, and which may be optionally benzofused if monocyclic. Each heterocycle consists of 25 one or more carbon atoms and from one to four heteroatoms selected from the group consisting of nitrogen, oxygen and sulfur. As used herein, the terms "nitrogen and sulfur heteroatoms" include any oxidized form of nitrogen and sulfur, and the quaternized form of any basic 30 nitrogen. A heterocyclyl radical may be attached at any endocyclic carbon or heteroatom which results in the creation of a stable structure. Preferred heterocycles include 5-7 membered monocyclic heterocycles and 8-10

1 or 2. In a preferred embodiment of this invention, these terms refer to the human immunodeficiency virus type 1 aspartyl protease.

The term "thiocarbamates" refers to compounds
5 containing the functional group N-SO₂-O.

Combinations of substituents and variables
envisioned by this invention are only those that result
in the formation of stable compounds. The term "stable",
as used herein, refers to compounds which possess
10 stability sufficient to allow manufacture and
administration to a mammal by methods known in the art.
Typically, such compounds are stable at a temperature of
40°C or less, in the absence of moisture or other
chemically reactive conditions, for at least a week.

15 This invention also envisions the quaternization of
any basic nitrogen-containing groups of the compounds
disclosed herein. The basic nitrogen can be quaternized
with any agents known to those of ordinary skill in the
art including, for example, lower alkyl halides, such as
20 methyl, ethyl, propyl and butyl chloride, bromides and
iodides; dialkyl sulfates including dimethyl, diethyl,
dibutyl and diamyl sulfates; long chain halides such as
decyl, lauryl, myristyl and stearyl chlorides, bromides
and iodides; and aralkyl halides including benzyl and
25 phenethyl bromides. Water or oil-soluble or dispersible
products may be obtained by such quaternization. The

The compounds of the present invention can be readily prepared by techniques known in the art. Scheme I illustrates a general synthetic route to the compounds of this invention.

SCHEME I

SCHEME II

5

In Step 1 of Scheme I, the bis protected amino acid is homologated through initial conversion to the Wienreb Amide (a) followed by alkylation with vinyl lithium (b) and stereoselective reduction (c). The diastereomers can be separated by silica gel chromatography (d). In step 2, the secondary alcohol is protected as a THP ether (e), as was found necessary for the oxidation step. The olefin was then oxidized to the aldehyde by ozone and the resulting ozonide reduced to the alcohol by sodium borohydride (steps f and g). After removal of the THP group (h) under acidic conditions the diol was converted to the epoxide (i, i' and i'') in one pot according to the method of Sharpless [K. B. Sharpless Tetrahedron 1992, 48 (35), pp. 10515-10530. The epoxide, 4, was then opened by H₂N-D' and further acylated in the presence of i-Pr₂Net by E-SO₂Cl to generate compounds of the formula schematically represented as 5. Alternate D' groups may be introduced at this point too. The synthesis of the D' as shown in compounds illustrated in Table II is shown in Scheme II.

These compounds could then be further manipulated by removal of the Bn group and introduction

of a variety of R⁸ groups by reacting with the
cooresponding alkyl halides. Further elaboration was
possible by removal of the t-Butyl carbonate (1) and
reintroduction of another group or carbamate designated
5 as A, to provide compounds represented as 6 (formula II).
We found that coupling as in reacton "m" was efficient
under the following general conditions: alkyl halide (R⁸-
Cl, 2.5 EQ. CsCO₃, dioxane, 80°C, 2-4 hours. Similar
alkylating conditions are reported in J. Med. Chem 1992,
10 1688 along with representative routes for the synthesis
of some R⁸-Cl intermediates. The coupling as illustrated
for bringing in A, step "o", was generally efficient
under the following conditions: activated p-NO₂-phenyl
carbonate (p-NO₂-O-A), i-Pr₂NEt, CH₂Cl₂, RT, 12 hours. Use
15 of the activated succinate provides an alternative
coupling reagent (Succinate-A).

Alternatively, compounds of the present invention
can also be prepared according to Scheme III below.

SCHEME III

Thus, the synthetic approach illustrated in Scheme I and Scheme III can be readily extended to produce other compounds of the present invention. The above synthetic schemes are not intended to comprise a comprehensive list of all means by which compounds described and claimed in this application may be synthesized. Further methods will be evident to those of ordinary skill in the art.

As discussed above, the novel compounds of the present invention are excellent ligands for aspartyl proteases, particularly HIV-1 and HIV-2 proteases. Accordingly, these compounds are capable of targeting and inhibiting late stage events in HIV replication, i.e., the processing of the viral polyproteins by HIV encoded proteases. Such compounds inhibit the proteolytic processing of viral polyprotein precursors by inhibiting

aspartyl protease. Because aspartyl protease is essential for the production of mature virions, inhibition of that processing effectively blocks the spread of virus by inhibiting the production of
5 infectious virions, particularly from chronically infected cells. Compounds according to this invention advantageously inhibit the ability of the HIV-1 virus to infect immortalized human T cells over a period of days, as determined by an assay of extracellular p24 antigen --
10 a specific marker of viral replication. Other anti-viral assays have confirmed the potency of these compounds.

The compounds of this invention may be employed in a conventional manner for the treatment of viruses, such as HIV and HTLV, which depend on aspartyl proteases for
15 obligatory events in their life cycle. Such methods of treatment, their dosage levels and requirements may be selected by those of ordinary skill in the art from available methods and techniques. For example, a compound of this invention may be combined with a
20 pharmaceutically acceptable adjuvant for administration to a virally-infected patient in a pharmaceutically acceptable manner and in an amount effective to lessen the severity of the viral infection.

Alternatively, the compounds of this invention may
25 be used in vaccines and methods for protecting individuals against viral infection over an extended period of time. The compounds may be employed in such vaccines either alone or together with other compounds of this invention in a manner consistent with the
30 conventional utilization of protease inhibitors in vaccines. For example, a compound of this invention may be combined with pharmaceutically acceptable adjuvants conventionally employed in vaccines and administered in

prophylactically effective amounts to protect individuals over an extended period time against HIV infection. As such, the novel protease inhibitors of this invention can be administered as agents for treating or preventing HIV
5 infection in a mammal.

The compounds of formula I, especially those having a molecular weight of less than about 700 g/mole, may be readily absorbed by the bloodstream of mammals upon oral administration. Compounds of formula I having a
10 molecular weight of less than about 600 g/mole are most likely to demonstrate oral availability. This surprisingly impressive oral availability makes such compounds excellent agents for orally-administered treatment and prevention regimens against HIV infection.

15 The compounds of this invention may be administered to a healthy or HIV-infected patient either as a single agent or in combination with other anti-viral agents which interfere with the replication cycle of HIV. By administering the compounds of this invention with other
20 anti-viral agents which target different events in the viral life cycle, the therapeutic effect of these compounds is potentiated. For instance, the co-administered anti-viral agent can be one which targets early events in the life cycle of the virus, such as cell
25 entry, reverse transcription and viral DNA integration into cellular DNA. Anti-HIV agents targeting such early life cycle events include, didanosine (ddI), alcitabine (ddC), d4T, zidovudine (AZT), polysulfated polysaccharides, sT4 (soluble CD4), ganciclovir,
30 dideoxycytidine, trisodium phosphonoformate, eflornithine, ribavirin, acyclovir, alpha interferon and trimenotrexate. Additionally, non-nucleoside inhibitors of reverse transcriptase, such as TIBO or nevirapine, may be

used to potentiate the effect of the compounds of this invention, as may viral uncoating inhibitors, inhibitors of trans-activating proteins such as tat or rev, or inhibitors of the viral integrase.

5 Combination therapies according to this invention exert a synergistic effect in inhibiting HIV replication because each component agent of the combination acts on a different site of HIV replication. The use of such combinations also advantageously reduces the dosage of a
10 given conventional anti-retroviral agent which would be required for a desired therapeutic or prophylactic effect as compared to when that agent is administered as a monotherapy. These combinations may reduce or eliminate the side effects of conventional single anti-retroviral
15 agent therapies while not interfering with the anti-retroviral activity of those agents. These combinations reduce potential of resistance to single agent therapies, while minimizing any associated toxicity. These combinations may also increase the efficacy of the
20 conventional agent without increasing the associated toxicity. In particular, we have discovered that these compounds act synergistically in preventing the replication of HIV in human T cells. Preferred combination therapies include the administration of a
25 compound of this invention with AZT, ddI, ddC or d4T.

Alternatively, the compounds of this invention may also be co-administered with other HIV protease inhibitors such as Ro 31-8959 (Roche), L-735,524 (Merck), XM 323 (Du-Pont Merck) and A-80,987 (Abbott) to increase
30 the effect of therapy or prophylaxis against various viral mutants or members of other HIV quasi species.

We prefer administering the compounds of this invention as single agents or in combination with

5

limited to, HTLV-I and HTLV-II. In addition, the compounds of this invention may also be used to inhibit other aspartyl proteases, and in particular, other human aspartyl proteases, including renin and aspartyl

5 proteases that process endothelin precursors.

15 buffer substances such as phosphates, glycine, sorbic acid, potassium sorbate, partial glyceride mixtures of saturated vegetable fatty acids, water, salts or electrolytes, such as protamine sulfate, disodium hydrogen phosphate, potassium hydrogen phosphate, sodium
20 chloride, zinc salts, colloidal silica, magnesium trisilicate, polyvinyl pyrrolidone, cellulose-based substances, polyethylene glycol, sodium carboxymethylcellulose, polyacrylates, waxes, polyethylene-polyoxypropylene-block polymers,
25 polyethylene glycol and wool fat.

30 administration or administration by injection. The pharmaceutical compositions of this invention may contain any conventional non-toxic pharmaceutically-acceptable carriers, adjuvants or vehicles. The term parenteral as

The pharmaceutical compositions may be in the form of a sterile injectable preparation, for example, as a sterile injectable aqueous or oleaginous suspension. This suspension may be formulated according to techniques known in the art using suitable dispersing or wetting agents (such as, for example, Tween 80) and suspending agents. The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally-acceptable diluent or solvent, for example, as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are mannitol, water, Ringer's solution and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose, any bland fixed oil may be employed including synthetic mono- or diglycerides. Fatty acids, such as oleic acid and its glyceride derivatives are useful in the preparation of injectables, as are natural pharmaceutically-acceptable oils, such as olive oil or castor oil, especially in their polyoxyethylated versions. These oil solutions or suspensions may also contain a long-chain alcohol diluent or dispersant such as Ph. Helv or a similar alcohol.

The pharmaceutical compositions of this invention may be orally administered in any orally acceptable dosage form including, but not limited to, capsules, tablets, and aqueous suspensions and solutions. In the case of tablets for oral use, carriers which are commonly used include lactose and corn starch. Lubricating

agents, such as magnesium stearate, are also typically added. For oral administration in a capsule form, useful diluents include lactose and dried corn starch. When aqueous suspensions are administered orally, the active ingredient is combined with emulsifying and suspending agents. If desired, certain sweetening and/or flavoring and/or coloring agents may be added.

The pharmaceutical compositions of this invention may also be administered in the form of suppositories for rectal administration. These compositions can be prepared by mixing a compound of this invention with a suitable non-irritating excipient which is solid at room temperature but liquid at the rectal temperature and therefore will melt in the rectum to release the active components. Such materials include, but are not limited to, cocoa butter, beeswax and polyethylene glycols.

Topical administration of the pharmaceutical compositions of this invention is especially useful when the desired treatment involves areas or organs readily accessible by topical application. For application topically to the skin, the pharmaceutical composition should be formulated with a suitable ointment containing the active components suspended or dissolved in a carrier. Carriers for topical administration of the compounds of this invention include, but are not limited to, mineral oil, liquid petroleum, white petroleum, propylene glycol, polyoxyethylene polyoxypropylene compound, emulsifying wax and water. Alternatively, the pharmaceutical composition can be formulated with a suitable lotion or cream containing the active compound suspended or dissolved in a carrier. Suitable carriers include, but are not limited to, mineral oil, sorbitan monostearate, polysorbate 60, cetyl esters wax, cetearyl

alcohol, 2-octyldodecanol, benzyl alcohol and water. The pharmaceutical compositions of this invention may also be topically applied to the lower intestinal tract by rectal suppository formulation or in a suitable enema
5 formulation. Topically-transdermal patches are also included in this invention.

The pharmaceutical compositions of this invention may be administered by nasal aerosol or inhalation. Such compositions are prepared according to techniques well-
10 known in the art of pharmaceutical formulation and may be prepared as solutions in saline, employing benzyl alcohol or other suitable preservatives, absorption promoters to enhance bioavailability, fluorocarbons, and/or other solubilizing or dispersing agents known in the art.

15 Dosage levels of between about 0.01 and about 100 mg/kg body weight per day, preferably between about 0.5 and about 50 mg/kg body weight per day of the active ingredient compound are useful in the prevention and treatment of viral infection, including HIV infection.
20 Typically, the pharmaceutical compositions of this invention will be administered from about 1 to about 5 times per day or alternatively, as a continuous infusion. Such administration can be used as a chronic or acute therapy. The amount of active ingredient that may be
25 combined with the carrier materials to produce a single dosage form will vary depending upon the host treated and the particular mode of administration. A typical preparation will contain from about 5% to about 95% active compound (w/w). Preferably, such preparations
30 contain from about 20% to about 80% active compound.

Upon improvement of a patient's condition, a maintenance dose of a compound, composition or combination of this invention may be administered, if

000000 4946560

necessary. Subsequently, the dosage or frequency of administration, or both, may be reduced, as a function of the symptoms, to a level at which the improved condition is retained when the symptoms have been alleviated to the
5 desired level, treatment should cease. Patients may, however, require intermittent treatment on a long-term basis upon any recurrence of disease symptoms.

As the skilled artisan will appreciate, lower or higher doses than those recited above may be required.
10 Specific dosage and treatment regimens for any particular patient will depend upon a variety of factors, including the activity of the specific compound employed, the age, body weight, general health status, sex, diet, time of administration, rate of excretion, drug combination, the
15 severity and course of the infection, the patient's disposition to the infection and the judgment of the treating physician.

The compounds of this invention are also useful as commercial reagents which effectively bind to aspartyl
20 proteases, particularly HIV aspartyl protease. As commercial reagents, the compounds of this invention, and their derivatives, may be used to block proteolysis of a target peptide or may be derivatized to bind to a stable resin as a tethered substrate for affinity chromatography
25 applications. These and other uses which characterize commercial aspartyl protease inhibitors will be evident to those of ordinary skill in the art.

30 acceptable derivatives or prodrugs thereof. A "pharmaceutically acceptable derivative" or "pharmaceutically acceptable prodrug" means any pharmaceutically acceptable salt, ester, salt of an

15 then allowed to warm to room temperature and stirred
overnight. After 18 hours at room temperature, the
reaction was cooled to 0°C, and quenched with 200 mL of a
5% sodium bicarbonate solution. The reaction was
extracted twice with EtOAc. The combined organics were
20 washed with five times with water, and then brine, dried
over MgSO₄, filtered and the solvent was removed *in vacuo*.
The yield was 28g of amide which was used as is.
HPLC (5-100% CH₃CN/water) showed 1 peak at 10.77 min and
the NMR (CDCl₃) was consistent with the expected

Example 5

BOC Benzyl Tyrosine Diol (THP protected)
(Scheme 1, steps f and g, compound 3)

THP protected BOC benzyl tyrosine allyl alcohol (1.5 g, 3.2 mmol) was dissolved in methanol (5 ml) and methylene chloride (20 mL) and cooled to -78°C . Ozone was bubbled into the stirred solution for 1.5 hours at -78°C . The solution was then flushed with nitrogen to remove the ozone. Sodium borohydride (920 mg, 25.6 mmol, 8 eq.) was then added in small portions over 5 minutes at -78°C . Methanol (35 mL) was added and the reaction was stirred at 78°C for 5 minutes; then was slowly warmed to 0°C . Vigorous bubbling began at $\sim -20^\circ\text{C}$. CH₃CN/water) showed 1 peak at 13.81 min and the proton NMR (CDCl₃) was consistent with structure as a mix of diastereomers (~1:1) at the THP alcohol.

Example 6

Epoxide (4)

THP-protected diol (3) (0.40 g, 0.85 mmol) was combined with a catalytic amount of *p*-toluenesulfonic acid (0.004 g) in methanol (20 mL) under a N₂ atmosphere. After stirring at room temperature for ca. 15 minutes, the initial white suspension dissolved completely. Stirring at room temperature was continued for ca. 1 hour, after which time complete disappearance of starting material (3) was confirmed by TLC. The solvent was removed *in vacuo* to give diol as a white solid, combined with residual *p*-toluenesulfonic acid. The crude diol was dissolved in anhydrous dichloromethane (15 mL), and trimethylorthoacetate (0.130 mL, 1.02 mmol) was added dropwise with stirring. Upon addition of trimethylorthoacetate, the cloudy solution became colourless. After stirring at room temperature for ca. 1 hour, TLC again indicated complete disappearance of starting material. The solvent was removed *in vacuo* to give the desired cyclic orthoacetate as a viscous white oil, which was re-dissolved in anhydrous DCM (15 mL). Trimethylsilyl chloride (0.129 mL, 1.02 mmol) was added dropwise with stirring. After 1.5 hours at room temperature generally no further starting material remained. The solvent was removed *in vacuo* to give the desired chloroacetates as a yellow oil, which was dissolved in methanol (20 mL). Cesium carbonate (0.48 g, 1.48 mmol) was added in one portion, and the solution was

000000-494690

stirred at room temperature for 2 hours, after which time, TLC confirmed the absence of any starting material. The solvent was removed *in vacuo* to give a pale yellow oil, which was partitioned between saturated aqueous ammonium chloride solution (30 mL) and DCM (30 mL). The organic layer was taken, and the aqueous layer re-extracted with DCM (2 x 30 mL). The combined organic extracts were dried over MgSO_4 , and the solvent removed *in vacuo* to give crude epoxide (4) as a yellow oil. This material was either used in the crude form, or could be purified by flash column chromatography (3:7 ethyl acetate/hexane to 4:1 ethyl acetate/methanol) to give epoxide (4) as a white solid: $R_f = 0.60$ (3:7 ethyl acetate/hexane); $^1\text{H NMR}$ (CDCl_3) 7.49-7.29 (5H, m), 7.14 (2H, d, $J = 8.3$ Hz), 6.93 (2H, d, $J = 8.3$ Hz), 5.05 (2H, s), 4.44 (1H, br. s), 3.64 (1H, br. s), 2.97-2.86 (2H, m), 2.85-2.72 (3H, m), 1.39 (9H, s); coupled LCMS showed the product as a single major peak with m/z 370 $[\text{M}+\text{H}]^+$ or m/z 312 $[\text{M}+\text{H}-\text{tBu}]^+$ at R_T 2.84 min; HPLC (205 nm) over an extended 20 minute run time showed the crude material to be a 9:1 mixture of diastereoisomeric epoxides at R_T s of 14.2 min. (*major diastereoisomer*) & 14.3 min. (*minor diastereoisomer*).

Example 7

Isobutylamino Alcohol (Scheme 1, step j)

Crude epoxide (4) (0.37 g, 0.85 mmol) was combined with isobutylamine (*large excess*, 4 mL) in ethanol (4 mL) under a N_2 atmosphere. The reaction mixture was heated to reflux with stirring for 2.5 hours. The solvent was removed *in vacuo* to give a pale yellow oily residue. Trituration with hexane gave the isobutylamino alcohol

General Procedure for Mitsunobu Alkylations of phenol scaffold A with various alcohols (205-218):

A solution of 2-5 equivalents each of triphenylphosphine and the appropriate alcohol in anhydrous dichloromethane (typically at a concentration of 0.05 M) was treated with di-*t*-butyl azodicarboxylate (2-5 equivalents). Polymer supported triphenylphosphine (Aldrich Chemical) was employed for examples 15-18 to facilitate removal of the triphenylphosphine oxide by-product. After stirring at RT for 5 minutes the solution was treated with 1 equivalent of solid (3*R*,3*aS*,6*aR*)hexahydrofuro[2,3-*b*]furan-3-yl (1*S*,2*R*)-3-[(1,3-benzodioxol-5-ylsulfonyl)(isobutyl)amino]-2-hydroxy-1-(4-hydroxybenzyl)propylcarbamate and stirring at RT was continued. When the reaction was determined to be complete by thin layer chromatography (2-18 hours) the solution was concentrated in vacuo and the residue purified by flash chromatography (silica gel,

hexane/EtOAc or dichloromethane/2M NH₃ in MeOH) to afford the desired product.

General procedure for reactions of primary amine
 scaffolds with various electrophiles (229-260): A
 solution of the primary amine (0.02 M) in anhydrous CH₂Cl₂
 at 0°C was treated with 1.5 equivalents of N,N-
 25 diisopropylethylamine (omitted for reactions with

isocyanates and isothiocyanates, examples 56-60) followed by 1.05 equivalent of the appropriate electrophile (acid chloride, chloroformate, sulfonyl chloride, carbamyl chloride, isocyanate, isothiocyanate). The resulting solution was allowed to warm to RT with stirring. When analysis by TLC indicated the reaction to be complete (2-18 hours) the solution was concentrated *in vacuo* and the residue subjected to flash chromatography (SiO₂, CH₂Cl₂/MeOH or hexane/EtOAc) to afford the desired product.

General procedure for the addition of BisTHF units

006090"4946560

To a solution of the product from the previous step (0.36 g, 0.57 mmol) in 20 mL of anhydrous dichloromethane was added dropwise trifluoroacetic acid (5 mL). The mixture was stirred for 1 hour at room temperature. The solvents were removed under reduced pressure; the residue was redissolved in 50 mL of dichloromethane and 30 mL of 10% aqueous sodium carbonate was added. The aqueous phase was separated and extracted with dichloromethane (2 x 25 mL). The combined organic phases were dried with sodium carbonate, filtered, and concentrated under reduced pressure. The residue was redissolved in 10 mL of acetonitrile. N-Ethyldiisopropylamine (0.15 g, 1.1 mmol) and (3R,3aS,6aR)-hexahydrofuro[2,3-b]furan-3-yl-4-nitrophenylcarbonate (0.20 g, 0.68 mmol) were added, and the solution was stirred for 12 hours. The solvents were removed under reduced pressure. The residue was redissolved in ethyl acetate (50mL), and the organic phase was extracted with water (30 mL) followed by 5% aqueous sodium carbonate solution (5 x 50 mL). The organic phase was dried with sodium carbonate, filtered, and concentrated under reduced pressure. The residue was purified on silica gel using ethyl acetate-hexanes [1] as eluent to provide the following compounds [Y:(2)]:

Antiviral activity assay in MT4 cells

Antiviral HIV activity and compound-induced cytotoxicity were measured in parallel by means of a propidium iodide based procedure in the human T-cell lymphotropic virus transformed cell line MT4. Aliquots of the test compounds were serially diluted in medium (RPMI 1640, 10% fetal calf serum (FCS), and gentamycin) in 96-well plates (Costar 3598) using a Cetus Pro/Pette. Exponentially growing MT4 cells were harvested and centrifuged at 1000 rpm for 10 min in a Jouan centrifuge (model CR 4 12). Cell pellets were resuspended in fresh medium (RPMI 1640, 20% FCS, 20% IL-2, and gentamycin) to a density of 5×10^5 cells/ml. Cell aliquots were infected by the addition of HIV-1 (strain IIIB) diluted to give a viral multiplicity of infection of 100 x TCID₅₀. A similar cell aliquot was diluted with medium to provide a mock-infected control. Cell infection was allowed to proceed for 1 hr at 37° in a tissue culture incubator with humidified 5% CO₂ atmosphere. After the 1 hr incubation the virus/cell suspensions were diluted 6-fold with fresh medium, and 125 µl of the cell suspension was added to each well of the plate containing pre-diluted compound. Plates were then placed in a tissue culture incubator with humidified 5% CO₂ for 5 days. At the end of the incubation period, 27 µl of 5% Nonidet-40 was added to each well of the incubation plate. After thorough mixing with a Costar multitip pipetter, 60 µl of

the mixture was transferred to filter-bottomed 96-well plates. The plates were analyzed in an automated assay instrument (Screen Machine, Idexx Laboratories). The assay makes use of a propidium iodide dye to estimate the DNA content of each well.

Anti-viral activity against Resistant Viruses

EP13 and D545701, two multi protease inhibitor resistant viruses were used to assess potency against mutant viruses. These viruses contain the following
10 mutations relative to the consensus sequence of wild type virus:

D545701-14: Protease amino acid sequence: L10I, L19Q, K20R, E35D, M36I, S37N, M46I, I50V, I54V, I62V, L63P,
15 A71V, V82A, L90M; reverse transcriptase amino acid sequence: E28K, K32E, V35I, T39S/T, E40D/V/Y/F, M41M/L, K43E, Y181Y/C

EP13: Protease amino acid sequence: M46I, L63P, A71V,
20 V82F/L, I84V; No reverse transcriptase mutations.

Reference data for the following protease inhibitors are (D545701-14; EP13):

Amprenavir™: >1000nM; 600nM
25 Indinavir™: 700nM; 560nM
Nelfinavir™: 690nM; N/A
Ritonavir™: >1000nM; >600nM
Saquinavir™: 900nM; N/A

30 Assays of the above mutant viruses were carried out as described above for the wild type virus and the results are shown below in Table B.
